### Introduction

next expressions allows to perform a wide variety of data manipulations on a JavaScript primitives, arrays and objects hosted by next REST server.

For example :

next expression	Explanation
<code>\$(person~X)</code>	resolves <u>person</u> object and produces XML from that object
<code>\$(fruits#S&amp;.)</code>	resolves <u>fruits</u> array, sorts array, joins all elements with comma

next expression definition :

```
$(JS_VAR_NAME)[action1][action2]...
```

Actions perform data manipulation. next engine evaluates actions from the left to right order. Every action in chain gets a value calculated by previous action in chain. Some actions in chain can be ignored in some cases. When actions chain is finished the last calculated value is assigned to whole expression.

JS\_VAR\_NAME is a name of a JavaScript variable in next source. If JS\_VAR\_NAME is not specified first action in chain will get an undefined value.

Action definition :

```
ACTION_ID[ACTION_VALUE]
```

In our first example above for `$(person~X)` expression, person is name of a JavaScript variable and ~X is an action, where ~ is ACTION\_ID ( object operation action ) and X is ACTION\_VALUE ( produce XML )

In the second example above for `$(fruits#S&.)` expression we have a fruits JavaScript variable and 2 actions in chain #S&, where #S action sorts fruits array and &. action joins array elements with comma.

Depending on ACTION\_ID, ACTION\_VALUE can be a string and/or another another next expression ( inner expression ). For example `$(test@$(value))` where @ is an ACTION\_ID and \$(value) is an ACTION\_VALUE. \$(value) is an expression itself and can contain its own actions next expressions can be nested with unlimited depth

Available actions :

ACTION_ID	Explanation
@	Default value. Applies for undefined values. For all other values is ignored. ACTION_VALUE can be a string and/or internal next expression(s).
:	Typecast. Performs typecast for primitive values. Also can convert any value to null or undefined. Available ACTION_ID + ACTION_VALUES are <pre>:num :str :bool :null :undefined</pre>
.	Object property resolution. Resolves property value for objects. Ignored for all other data types. ACTION_VALUE can be a string and/or internal next expression(s).
	Object operations. Performs different operations with JavaScript objects. Ignored for all other data types. Available ACTION_ID + ACTION_VALUES are

~	~K ( resolves object keys ) ~V ( resolves object values ) ~O ( converts to object ) ~X ( produces XML ) ~Y ( produces YAML ) ~P ( produces key-value pairs )
<	Object key reverse resolution. Resolves a key of JavaScript object by its value. Ignored for all non object types. ACTION_VALUE can be a string and/or internal next expression(s).
#	Array operations. Performs different operations with JavaScript arrays. All other data types are ignored. Available ACTION_ID + ACTION_VALUES are #S ( sorts asc ) #s ( sorts desc ) #U ( unique values ) #D ( duplicate values ) #LEN ( elements count ) #A ( converts to array ) #F ( gets first array element or undefined )
&	Joins JavaScript array elements with ACTION_VALUE. Ignored for all other data types. ACTION_VALUE can be a string and/or internal next expression(s).
+	Add/Merge action. Adds elements to existing JavaScript array or merges two JavaScript objects. Ignores for all other data types. For JavaScript arrays ACTION_VALUE can be a string and/or internal next expression(s). For JavaScript object ACTION_VALUE must be internal next expression which is evaluated to JavaScript object
-	Eliminates items from JavaScript arrays or JavaScript objects. Ignored for all other data types. ACTION_VALUE can be a string and/or internal next expression(s).
^	String operations Available ACTION_ID + ACTION_VALUES are ^U ( upper case ) ^U1 ( capitalizes first letter ) ^L ( lower case ) ^T ( trims ) ^LEN ( length )
!	Undefined value operations !E Converts empty strings, empty arrays and empty objects to undefined !U Evaluates the whole expression to undefined if one of the sub expressions is evaluated to undefined
*	Mandatory value validator action. Throws exception for undefined values. You can provide a custom error message as ACTION_VALUE ( including inner next expressions )
	Pushes current value to function parameters stack. Doesn't have an ACTION_ID

The following characters are reserved for future actions and must be always escaped in next expressions

```
%
>
=
?
```

There are 3 additional actions :

```
Accessing array elements [ â€¦ ]
Substring [ â€¦ ]
Function call (...)
```

Actions can be combined in any order without any limit. Actions count is also unlimited.

Please note ACTION\_IDS must be escaped if they are used in ACTION\_VALUES

### Resolving a JavaScript variable value

The `$(distanceToMoon)` expression resolves a `distanceToMoon` variable value. This variable can be JavaScript primitive, array or object.

If `distanceToMoon` variable is not defined expression will be evaluated to undefined.

Empty expressions `$()` are also evaluated to undefined

next expression(s) can be a part of some string. For example :

```

1 |
2 | sites = ['google.com', 'w3schools.com', 'facebook.com'];
3 | urlTemplate = 'http://www.${sites}';
4 |

```

The `$(urlTemplate)` expression is evaluated to following array

```

1 |
2 | ["http://www.google.com", "http://www.w3schools.com", "http://www.facebook.com"]
3 |

```

## Default values action @

**ACTION\_ID** is @

**ACTION\_VALUE** can be a string and/or next expression(s)

Applies for undefined values

This action replaces undefined values with value you provide in **ACTION\_VALUE**.

Example :

```
$(distanceToMoon@384400)
```

If the `distanceToMoon` variable is not defined next engine will apply a '384400' default value. The '384400' value is treated as string by default, but you can cast it to a number in the following way ( see more about typecast in next section )

```
$(distanceToMoon@384400:num)
```

The `$(@384400)` expression is always evaluated to '384400' because a `${}` expression is evaluated to undefined value and '384400' default value is applied

The following expression is evaluated to empty string :

```
$(@)
```

The default value can be a next expression itself. For example :

```
$(distanceToMoon@$(calcDistance))
```

If the `distanceToMoon` is undefined next engine will apply a default value provided by `$(calcDistance)` inner expression

If the `$(calcDistance)` expression is also evaluated to `undefined` you can provide an additional default value(s) :

```
$(distanceToMoon@$(calcDistance)@{val1}@{val2}@384400)
```

Default value can be mixed of text and inner next expression(s). For example :

```
$(@Hello ${world} 2017)
```

The 'Hello \${world} 2017' is a default value which contains inner next expression

## Typecast :

**ACTION\_ID** is :

**ACTION\_VALUE** can be one of the following `num`, `str`, `bool`, `null`, `undefined`

Applies for anything ( num, str, bool are applied for primitives; null, undefined for anything )

The following type casts are available

ACTION_ID + ACTION_VALUE	Description	Example
:num	Casts string or boolean values to a number. All other data types are ignored. Illegal numbers are casted to undefined	<code>\$(stringItem:num)</code>
:str	Casts boolean or numeric values to a string. All other data types are ignored.	<code>\$(boolItem:str)</code>
:bool	Casts numeric or string values to boolean. All other data types are ignored. Zero numbers are casted to false, non zero numbers casted to true. 'true' string values are casted to true, 'false' string values are casted to false. All other string items are casted to undefined	<code>\$(numericItem:bool)</code>
:null	Any value of any type is converted to null	<code>\$(array1:null)</code>
:undefined	Any value of any type is converted to undefined	<code>\$(obj1:undefined)</code>

### Typecast examples

next expression	Explanation
<code>\$(@)</code>	Is evaluated to empty string.  Empty expression <code>\$(@)</code> is evaluated to undefined value. Therefore default value action is applied here. In this expression <code>\$(@)</code> default value it an empty string

<code>\${@319:num}</code>	Casts a '319' string value to numeric
<code>\${@:num}</code>	Casts an empty string to numeric ( result is undefined )
<code>\${@319:bool}</code>	Casts a '319' string value to boolean ( result is undefined )
<code>\${@319:bool@hello}</code>	Casts a '319' string value to boolean. The result is undefined. Therefore the second default value action is applied. Final result is 'hello' string
<code>\${@319:num:bool}</code>	First casts a '319' string value to numeric, then casts a 319 numeric value to boolean ( result is true )
<code>\${@true:bool}</code>	Casts a 'true' string value to boolean ( result is true )
<code>\${:null}</code>	Converts an undefined value to null
<code>\$(obj1:null)</code>	Converts obj1 to null
<code>\$(obj1:num)</code>	If the obj1 is not a primitive value this casting action will be ignored. :num, :str and :bool actions are applied only for primitives

### Object property resolution .

ACTION\_ID is .

ACTION\_VALUE can be a string and/or next expression(s)

Applies for objects

This action resolves object properties.

For example the `$(person.city)` expression resolves a `city` property of `person` object where dot is an ACTION\_ID and 'city' is ACTION\_VALUE.

`_this_` and `_parent_` are reserved variable names ( do not declare variables with those names in your next sources )

`_this_` points to a current object instance.

`_parent_` points to a parent object instance.

Let's consider few examples for the following next source code snippet

```

1
2 prop1 = 'address';
3
4 props = ['name','age'];
5
6 person = {
7   name: 'Alex',
8   age: 25,
9   address: {
10    country: 'Canada',
11    city: 'Toronto'
12  }
13 };
14

```

next expression	Explanation and result
<code>\$(person.name)</code>	Resolves a <code>name</code> property of <code>person</code> object.  The result is 'Alex'
<code>\$(person.address.city)</code>	First resolves a <code>person</code> object, then resolves an <code>address</code> property of that object and finally resolves a <code>city</code> property from address object.  The result is 'Toronto'
<code>\$(person.{\$prop1}.country)</code>	First resolves a <code>person</code> object. Then resolves its property provided by <code>\$(prop1)</code> internal next expression which is 'address'. Finally resolves a <code>country</code> property of that object  The result is 'Canada'
<code>\$(person.{\$prop2})</code>	First resolves a <code>person</code> object. Then resolves its property which is provided by <code>\$(prop2)</code> internal next expression. The <code>prop2</code> variable is not declared therefore it's evaluated to undefined. next engine skips undefined values when performing object property resolution. So the <code>\$(prop2)</code> will be skipped and the whole expression will be equaled to a person object  The result is <code>person</code> object
<code>\$(person.{\$prop2@})</code>	First resolves a <code>person</code> object. Then resolves its property provided by <code>\$(prop2@)</code> internal expression. The <code>prop2</code> variable is not declared and evaluated to undefined. The <code>\$(prop2@)</code> expression has a default value action with is empty string value. Therefore <code>\$(prop2@)</code> expression will be evaluated to empty string. <code>person</code> object doesn't have an empty string property. That's why the whole expression will be evaluated to undefined  The result is

	undefined
<code>`\${person}.\${props}`</code>	<p>First resolves a <u>person</u> object. Then resolves its property provided by <code>`\${props}`</code> internal expression. The <code>`\${props}`</code> expression is evaluated to JavaScript array. Therefore next engine performs property resolution for each array element</p> <p>The result is ['Alex', 25]</p>

Let's consider examples for `_this_` and `_parent_` reserved variable names. next source code snippet is

```

1  dirs = {
2    ROOT_DIR: '/home/project',
3    HOME_DIR: `${_this_.ROOT_DIR}/next`,
4
5    SUBDIRS: {
6      LOGS_DIR: `${_parent_.ROOT_DIR}/LOGS`,
7      BACKUP_DIR: `${_parent_.HOME_DIR}/BACKUP`,
8      SUPER_BACKUP_DIR: `${_this_.BACKUP_DIR}/SUPER`
9    },
10
11    FILES: {
12      SERVER_LOG: `${_parent_.SUBDIRS.LOGS_DIR}/server.log`,
13      BACKUP_LOG: `${_parent_.SUBDIRS.SUPER_BACKUP_DIR}/backup.log`,
14      START_SCRIPT: `${_parent_.HOME_DIR}/start.sh`
15    }
16  };
17
18

```

next expression	Explanation and result
<code>`\${dirs.ROOT_DIR}`</code>	<p>First resolves a <u>dirs</u> object and then resolves its <u>ROOT_DIR</u> property</p> <p>The result is '/home/project'</p>
<code>`\${dirs.HOME_DIR}`</code>	<p>First resolves a <u>dirs</u> object and then resolves its <u>HOME_DIR</u> property. <u>HOME_DIR</u> contains a <code>`\${_this_.ROOT_DIR}`</code> next expression. In this expression <u>this_</u> points to <u>dirs</u> object instance. Therefore <code>`\${_this_.ROOT_DIR}`</code> is equals to a <code>`\${dirs.ROOT_DIR}`</code> expression</p> <p>The result is '/home/project/next'</p>
<code>`\${dirs.SUBDIRS.BACKUP_DIR}`</code>	<p>This expression is evaluated to a string value which contains a <code>`\${_parent_.HOME_DIR}`</code> sub expression <u>_parent_</u> points to a <u>dirs</u> object instance, therefore <u>HOME_DIR</u> is resolved as a property of <u>dirs</u> object</p> <p>The result is '/home/project/next/BACKUP'</p>
<code>`\${dirs.SUBDIRS.SUPER_BACKUP_DIR}`</code>	<p>This expression is evaluated to a string which contains a <code>`\${_this_.BACKUP_DIR}`</code> sub expression <u>_this_</u> points to <u>dirs.SUBDIRS</u> object instance, therefore <u>BACKUP_DIR</u> dir will be resolved as a property of <u>dirs.SUBDIRS</u> object</p> <p>The result is '/home/project/next/BACKUP/SUPER'</p>
<code>`\${dirs.FILES.BACKUP_LOG}`</code>	<p>The result is '/home/project/next/BACKUP/SUPER/backup.log'</p>
<code>`\${dirs.SUBDIRS._parent_.FILES._this_.START_SCRIPT}`</code>	<p>This examples shows a complex usage of <u>_this_</u> and <u>_parent_</u> pointers.</p> <p>The result is '/home/project/next/start.sh'</p>

## Object operations ~

ACTION\_ID is ~

ACTION\_VALUE can be one of the following K, V, O, X, Y, P

Applies for objects ( except of O which applies for anything )

Object operations action performs different kind of data manipulations with JavaScript objects in next expression

ACTION_ID + ACTION_VALUE	Description	Example
~K	<p>Resolves object key set as array. If the current value for this action is not an object action will be ignored.</p> <p>In this example first next engine resolves a <code>obj1</code> JavaScript variable and if it's a JavaScript object, resolves its key set as array</p>	<code>`\${obj1~K}`</code>

~V	<p>Resolves all object values as array ( including sub values ). If the current value for this action is not an object action will be ignored.</p> <p>In this example first next engine resolves a <u>obj1</u> JavaScript variable and if it's a JavaScript object, resolves all its values as array</p>	<code>#{obj1~V}</code>
~O	<p>Converts current value to object if it's not already an object. This action is ignored for objects</p> <p>In this example first next engine resolves an <u>item</u> JavaScript variable and if it's not a JavaScript object, converts it to the object in the following way :</p> <pre> 1 2 - { 3   "item": ITEM_VALUE 4 } 5 </pre> <p>where <u>ITEM_VALUE</u> is a value which was resolved before</p> <p><u>undefined</u> values are converted to empty objects</p>	<code>#{item~O}</code>
~X	<p>Produces an XML from object. This action is ignored for objects</p> <p>In this example first next engine resolves a <u>obj1</u> JavaScript variable and if it's a JavaScript object, produces an XML from that object</p>	<code>#{obj1~X}</code>
~Y	<p>Produces a YAML from object. This action is ignored for objects</p> <p>In this example first next engine resolves a <u>obj1</u> JavaScript variable and if it's a JavaScript object, produces a YAML from that object</p>	<code>#{obj1~Y}</code>
~P	<p>Produces a key=values pairs from object ( property file ). This action is ignored for objects</p> <p>In this example first next engine resolves a <u>obj1</u> JavaScript variable and if it's a JavaScript object, produces a key=value pairs from that object</p>	<code>#{obj1~P}</code>

Let's consider few examples for the following next source code snippet :

```

1
2 - person = {
3   name: 'Alex',
4   age: 25,
5   country: 'Canada'
6 };
7

```

next expression	Explanation and result
<code>#{person~K}</code>	<p>Resolves key set of <u>person</u> object as array</p> <p>The result is</p> <pre> 1 2 ["name", "age", "country"] 3 </pre>
<code>#{person~V}</code>	<p>Resolves values as of <u>person</u> object as array</p> <p>The result is</p> <pre> 1 2 ["Alex", 25, "Canada"] 3 </pre>
<code>#{person~O}</code>	<p>This action is ignored because <u>person</u> is already object</p>
<code>#{person.name~O}</code>	<p>First next engine resolves a <u>person</u> object, then resolves a <u>name</u> property of that object and ~O action converts last result to object</p> <p>The result is</p> <pre> 1 2 - { 3   "person.name": "Alex" 4 } 5 </pre>

## Object key reverse resolution <

ACTION\_ID is <

ACTION\_VALUE can be a string and/or next expression(s)

Applies for objects

Object key reverse resolution is a way to resolve an object keys by value(s)

Let's say we have the following object

```

1
2 - person = {
3   name: 'Alex',

```

```

4   age: 25,
5   country: 'Canada'
6 };
7

```

The `$(obj1)` expression resolves a `obj1` object. If we add an object key reverse resolution action to this expression `$(obj1<Alex)` it will resolve all object keys which contain 'Alex' string value ( 'Alex' is an ACTION\_VALUE ).  
The `$(obj1<Alex)` expression is evaluated to [ 'name' ] array.

Object key reverse resolution action always produces an array. Array can be empty if there is no matching result.

The following expression will be evaluated to empty array

```
$(obj1<25)
```

It happens because 25 is treated as string and not as numeric. To provide a numeric constant value use the following internal expression `$(@25:num)` which casts '25' string value to numeric

The final expression is

```
$(obj1<$(@25:num))
```

And it will be evaluated to [ 'age' ] array

Additionally it's possible to provide a multiple values for object key reverse resolution action by using array.  
Let's declare the following array in our next source :

```

1 |
2 | arr1 = [25, 'Canada', true];
3 |

```

And the following expression `$(obj1<$(arr1))` will be evaluated to

```
['age', 'country']
```

## Array operations #

**ACTION\_ID** is #

**ACTION\_VALUE** can be one of the following S, s, U, D, LEN, A, F

Applies for arrays ( except of A which applies for anything )

Array operations perform different kind of data manipulations with JavaScript arrays in next expression

ACTION_ID + ACTION_VALUE	Description	Example
#S	Sorts array in ascending order. If the current value for this action is not an array action will be ignored.  In this example first next engine resolves a <code>arr1</code> JavaScript variable and if it's a JavaScript array, sorts it in ascending order	<code>\$(arr1#S)</code>
#s	Same as previous action, but sorts in a descending order	<code>\$(arr1#s)</code>
#U	Eliminates all duplicate values from array making array values unique. If the current value for this action is not an array action will be ignored.  In this example first next engine resolves a <code>arr1</code> JavaScript variable and if it's a JavaScript array, removes all duplicate values from that array	<code>\$(arr1#U)</code>
#D	Resolves all repeated (duplicate) items in array. If the current value for this action is not an array action will be ignored.  In this example first next engine resolves a <code>arr1</code> JavaScript variable and if it's a JavaScript array, resolves duplicate values only in this array	<code>\$(arr1#D)</code>
#LEN	Calculates array length. If the current value for this action is not an array action will be ignored.  In this example first next engine resolves a <code>arr1</code> JavaScript variable and if it's a JavaScript array, calculates his length	<code>\$(arr1#LEN)</code>
#A	Converts any item to array if it's not already an array. If the current value for this action is an array action will be ignored.  For example if the item = 'test', the result will be a [ 'test' ]	<code>\$(item#A)</code>
#F	Resolves the first array element if array has only one element, or <u>undefined</u> value if array is empty or has more than one element. If the current value for this action is not an array action will be ignored.  In this example first next engine resolves a <code>arr1</code> JavaScript variable. If it's a JavaScript array and has only one element, resolves that element. But if that array is empty or has more than one element, makes the result <u>undefined</u>	<code>\$(arr1#F)</code>

Let's consider few examples for the following next source code snippet

```

1 |
2 | fruits = ['Mango', 'Banana', 'Apple', 'Banana'];

```

```
3
4 primitiveVar = 'test';
5
6
7 person = {
8   name: 'Alex',
9   age: 25,
10  country: 'Canada'
11};
```

next expression	Explanation and result
<code>\${fruits}</code>	Just resolves a <u>fruits</u> array as is The result is <pre>1 2 ["Mango", "Banana", "Apple", "Banana"] 3</pre>
<code>\${fruits#S}</code>	<u>fruits</u> array is sorted in ascending order The result is <pre>1 2 ["Apple", "Banana", "Banana", "Mango"] 3</pre>
<code>\${fruits#U}</code>	Duplicate values are removed from <u>fruits</u> array, all items in fruits array become unique The result is <pre>1 2 ["Mango", "Banana", "Apple"] 3</pre>
<code>\${fruits#D}</code>	Not a duplicate values are removed from <u>fruits</u> array The result is <pre>1 2 ["Banana"] 3</pre>
<code>\${fruits#A}</code>	This action is ignored because fruits is already an array The result is <pre>1 2 ["Mango", "Banana", "Apple", "Banana"] 3</pre>
<code>\${fruits#F}</code>	<u>fruits</u> array has 4 elements, therefore it is evaluated to undefined value The result is <pre>1 2 undefined 3</pre>
<code>\${fruits#U#s}</code>	First eliminates duplicate values and then sorts in descending order The result is <pre>1 2 ["Mango", "Banana", "Apple"] 3</pre>
<code>\${primitiveVar#S}</code>	This is evaluated to 'test' string because <u>primitiveVar</u> is not a JavaScript array but a string. Therefore array action is ignored
<code>\${person~V#LEN}</code>	1) next engine resolves a <u>person</u> JavaScript variable which is object 2) Applies a ~V action for that object. This action resolves all object values as array 3) Applies a #LEN action for that array which calculates its length The result is <pre>3</pre>

Joining array elements &

ACTION\_ID is &  
ACTION\_VALUE can be a string and/or next expression(s)  
Applies for arrays

This action joins all array elements with ACTION\_VALUE delimiter.

Let's consider few examples for the following next source code snippet

```
1
2 fruits = ['Mango', 'Banana', 'Apple', 'Banana'];
3 delimiter = ',';
4
```

next expression	Explanation and result
<code>© fruits 0 1</code>	Joins elements of <u>fruits</u> array with comma.

<code>\$(fruits&amp;)</code>	The result is <code>Mango,Banana,Apple,Banana</code>
<code>\$(fruits&amp;\${delimiter})</code>	Joins elements of <code>fruits</code> array with value provided by <code>\$(delimiter)</code> expression, i.e. with asterisk character The result is <code>Mango*Banana*Apple*Banana</code>
<code>\$(fruits&amp;\*)</code>	Joins elements of <code>fruits</code> array with asterisk character. The asterisk character is escaped not to be treated as a mandatory value action The result is <code>Mango*Banana*Apple*Banana</code>
<code>\$(fruits&amp;\n)</code>	Joins elements of <code>fruits</code> array with LF character The result is <code>Mango Banana Apple Banana</code>
<code>\$(fruits&amp;\t)</code>	Joins elements of <code>fruits</code> array with TAB character The result is <code>Mango Banana Apple Banana</code>
<code>\$(fruits&amp;\n\${delimiter})</code>	Joins elements of <code>fruits</code> array with LF and asterisk characters The result is <code>Mango *Banana *Apple *Banana</code>

### Add/Merge action +

ACTION\_ID is +

ACTION\_VALUE can be a string and/or next expression(s)

Applies for JavaScript arrays and objects

By using add/merge action you can add new elements to array or merge two objects.

This action is ignored for all other data types ( works only with arrays and objects )

Let's consider few examples regarding to arrays for the following next source code snippet

```

1 |
2 | fruits = ['Mango', 'Banana', 'Apple'];
3 |
4 | vegetables = ['Tomato', 'Cabbage'];
5 |
6 | vegetablePrices = {
7 |   Tomato: 15,
8 |   Cucumber: 8
9 | };
10 |
11 | greeting = 'Hello';
12 |

```

next expression	Explanation and result
<code>\$(fruits+Annona)</code>	First next engine resolves a <code>fruits</code> JavaScript array and then adds a 'Annona' string element to the end of fruits array + is ACTION_ID Annona is ACTION_VALUE ( string by default ) The result is <pre>1   2   ["Mango", "Banana", "Apple", "Annona"] 3  </pre>
<code>\$(fruits+Annona+Kiwi+Orange&amp;.)</code>	Annona, Kiwi and Orange are added to <code>fruits</code> array and then all array elements are joined with comma The result is <code>Mango,Banana,Apple,Annona,Kiwi,Orange</code>
<code>\$(fruits+\${vegetables})</code>	The <code>\$(vegetables)</code> inner expression is evaluated to array and it is added to the end of <code>fruits</code> array The result is <pre>1   2   ["Mango", "Banana", "Apple", "Tomato", "Cabbage"] 3  </pre>
<code>\$(fruits+\${@79:num})</code>	The 79 numeric value is added to <code>fruits</code> array because the <code>\$(@79:num)</code> expression is evaluated to 79 numeric The result is <pre>1  </pre>

	<pre> 2  ["Mango", "Banana", "Apple", 79] 3 </pre>
<pre>     \${@Annona#A+\${fruits}} </pre>	<p>1) <code>\${@Annona}</code> expression is evaluated to a 'Annona' string value ( see default value section )</p> <p>2) The <code>\${@Annona#A}</code> expression has a #A action which converts a 'Annona' string value to ['Annona'] array</p> <p>3) Adding <code>fruits</code> array to the end of ['Annona'] array</p> <p>The result is</p> <pre> 1  ["Annona", "Mango", "Banana", "Apple"] 2 3 </pre>
<pre>     \${fruits+\${vegetablePrices~K}} </pre>	<p>The <code>\${vegetablePrices~K}</code> inner expression resolves a key set of <code>vegetablePrices</code> object as array which are adds that array to the end of <code>fruits</code> array</p> <p>The result is</p> <pre> 1  ["Mango", "Banana", "Apple", "Tomato", "Cucumber"] 2 3 </pre>
<pre>     \${greeting+World} </pre>	<p><code>greeting</code> is not a JavaScript array or object therefore this action is ignored</p> <p>The result is</p> <pre>     'Hello' </pre>

#### Merging objects examples

nextl expression	Explanation and result
<pre>     \${obj1+\${obj2}} </pre>	<p>If <code>obj1</code> and <code>obj2</code> are JavaScript objects the <code>obj2</code> will be merged to a <code>obj1</code>. Otherwise this action will be ignored.</p> <p>nextl engine performs a deep merge for all sub elements of each object</p>
<pre>     \${obj1+test} </pre>	<p>If <code>obj1</code> is a JavaScript object this action will be ignored because 'test' is a primitive string and cannot be merged to an object</p>

#### Eliminate -

ACTION\_ID is -

ACTION\_VALUE can a be primitive or array

Applies for arrays and objects

This action eliminates item(s) from JavaScript arrays or objects.

Examples

nextl source and expression	Explanation and result
<p>nextl source</p> <pre> 1  fruits = ["Mango", "Banana", "Apple"]; 2 3 </pre> <p>nextl expression</p> <pre>     \${fruits-Banana-Apple} </pre>	<p>The 'Banana' and 'Apple' string items are eliminated from <code>fruits</code> array</p> <p>The result is</p> <pre> 1  ["Mango"] 2 3 </pre>
<p>nextl source</p> <pre> 1  mixedArray = [25, 'hello', true, 79]; 2 3 </pre> <p>nextl expression</p> <pre>     \${mixedArray-\${@25:num}} </pre>	<p>The 25 numeric element is eliminated from <code>mixedArray</code>.</p> <p><code>\${mixedArray-25}</code> expression will not eliminate a 25 element because it's treated as '25' string. Therefore we need to use an internal expression which supplies us with a numeric value <code>\${@25:num}</code></p> <p>The result is</p> <pre> 1  ["hello", true, 79] 2 3 </pre>
<p>nextl source</p> <pre> 1  fruits = ["Mango", "Lemon", "Banana", "Apple"]; 2 3  sourFruits = ["Lemon", "Apple"]; 4 5 </pre> <p>nextl expression</p> <pre>     \${fruits-\${sourFruits}} </pre>	<p>All items in <code>sourFruits</code> array are eliminated from <code>fruits</code> array</p> <p>The result is</p> <pre> 1  ["Mango", "Banana"] 2 3 </pre>
<p>nextl source</p> <pre> 1  fruits = ["Mango", undefined, "Apple"]; 2 3 </pre>	<p>The <code>\${}</code> expression is evaluated to <u>undefined</u>. All undefined items are eliminated from <code>fruits</code> array</p> <p>The result is</p>

next expression <code>\$(fruits-{})</code>	<pre>1   ["Mango", "Apple"] 2   3  </pre>
next source <pre>1   2   fruits = ['Mango', undefined, null, 'Apple']; 3  </pre>	The <code>\$.:null</code> expression is evaluated to <u>null</u> . All null items are eliminated from <u>fruits</u> array  The result is <pre>1   2   ["Mango", undefined, "Apple"] 3  </pre>
next expression <code>\$(fruits-\$.:null)</code>	
next source <pre>1   2   car = { 3     name: 'BMW', 4     model: '501', 5     price: 999 6   }; 7  </pre>	The <u>price</u> property is eliminated from <u>car</u> object  The result is <pre>1   2   car = { 3     name: 'BMW', 4     model: '501' 5   }; 6  </pre>
next expression <code>\$(car-price)</code>	

## String operations ^

ACTION\_ID is ^

ACTION\_VALUE can be one of the following U, U1, LEN, T

Applies for strings

String operations action allows to perform basic manipulations with JavaScript strings.

Let's consider each operation with examples in the table followed by this next source code snippet

```
1 |
2 | greeting = 'Hello, World !';
3 |
4 | text = 'I can do it';
5 |
6 | untrimmedText = ' I can do it ';
7 |
```

ACTION_ID + ACTION_VALUE	Example	Description
^U	<code>\$(greeting^U)</code>	Upper cases a string  The ^L action converts a <u>greeting</u> string to uppercase letters. For all other data types this action is ignored  The result is <code>'HELLO, WORLD !'</code>
^U1	<code>\$(text^U1)</code>	Capitalizes first letter in string  The ^U1 action capitalizes a first letter in the <u>text</u> string. For all other data types this action is ignored  The result is <code>'I can do it'</code>
^L	<code>\$(greeting^L)</code>	Lower cases a string  The ^L action converts the <u>greeting</u> string to lowercase letters. For all other data types this action is ignored  The result is <code>'hello, world !'</code>
^T	<code>\$(untrimmedText^T)</code>	Trims a string  The ^T action trims the <u>untrimmedText</u> string. For all other data types this action is ignored  The result is <code>'I can do it'</code>
^LEN	<code>\$(greeting^LEN)</code>	Calculates string length  The ^LEN action calculates a length of the <u>greeting</u> string. For all other data types this action is ignored  The result is <code>14</code>

## Undefined value operations !

ACTION\_ID is !  
ACTION\_VALUE can be one of the following U, E

ACTION_ID + ACTION_VALUE	Purpose	Example	Explanation and result
!E	Converts empty strings, empty arrays and empty objects to <u>undefined</u>	<p>next source</p> <pre>1 2 emptyStr = ""; 3 emptyArr = []; 4 emptyObj = {}; 5</pre> <p>next expressions</p> <pre>{emptyStr!E} {emptyArr!E} {emptyObj!E}</pre>	For all those 3 expressions result is <u>undefined</u>
!U	Evaluates next expression to <u>undefined</u> if one of the sub expressions is evaluated to <u>undefined</u>	<p>next source</p> <pre>1 2 text = 'My name is \${name}'; 3</pre> <p>next expression</p> <pre>{text!U}</pre>	The <u>text</u> JavaScript variable is referencing to a string value which contains a <u>\${name}</u> sub expression. If the <u>\${name}</u> expression is evaluated to undefined value, the <u>{text!U}</u> expression will be also evaluated to <u>undefined</u> value.

### Mandatory value validator \*

ACTION\_ID is \*  
ACTION\_VALUE can be a string and/or next expression(s)  
Applies for for undefined values

Mandatory value validator action throws error for undefined values. You can provide a custom error message in ACTION\_VALUE including sub expressions

Let's consider few examples for the following next source code snippet

```
1
2 item = 'test';
3 fruits = [];
4 car = {
5   name: 'BMW',
6   model: '501',
7   price: 999
8 };
9
```

next expression	Explanation and result
{item*}	In this case mandatory value validator is ignored because <u>item</u> JavaScript variable is not equals to <u>undefined</u>
{someUndeclaredVar*}	<p>The <u>someUndeclaredVar</u> JavaScript variable is not declared in next source, therefore we will get the following error message :</p> <p>The [{someUndeclaredVar}] expression cannot be evaluated to undefined ( it has a mandatory value validator ). Probably you have to provide it as external arg or check why it calculated to undefined</p>
{text*Please provide a text variable}	<p>The <u>text</u> JavaScript variable is not declared in next source. We will get a custom error message provided in next expression :</p> <p>Please provide a text variable</p>
{fruits*}	In this case mandatory value validator action is ignored because <u>fruits</u> is not equals to <u>undefined</u>
{fruits!E*Fruits array is empty}	<p>1) Resolving <u>fruits</u> array as <u>{fruits}</u>  2) Applying a !E action. This action converts empty arrays to <u>undefined</u> value. <u>fruits</u> array is empty, so we get an <u>undefined</u> value  3) Mandatory value validator throw error because it got an <u>undefined</u> value</p> <p>Fruits array is empty</p>
{car<\${model}!E*car object doesn't contain a /\${model@}/ model}	<p>1) Resolves <u>car</u> object as <u>{car}</u>  2) Performs object key reverse resolution for <u>car</u> object with <u>{model}</u> value as <u>{car&lt;\${model}}</u>  3) The <u>model</u> JavaScript variable is not declared in next source, therefore we get an empty array as a result  4) !E action converts an empty array to <u>undefined</u> value  5) Mandatory value validator throws custom error message because of <u>undefined</u> value  6) Custom error message has internal next expression</p> <p>car object doesn't contain a /\${model@}/ model  <u>{model@}</u> is evaluated to empty string</p> <p>The result is</p> <p>car object doesn't contain a // model</p>

<code>\${car.color*^L~O}</code>	1) Resolves <u>car</u> object 2) Resolves a <u>color</u> property of <u>car</u> object 3) The <u>color</u> property is not a member of <u>car</u> object therefore we get an <u>undefined</u> value 4) Mandatory value validator throws error because of <u>undefined</u> value  If the <u>color</u> property were a part of <u>car</u> object, mandatory value validator would be skipped and all actions after it would be performed
---------------------------------	---

## Accessing array elements [...]

**ACTION\_ID** is [ which ends with ]  
**ACTION\_VALUE** is located between [...] square brackets  
Applies for arrays ( and strings )

Array elements can be accessed by their indexes. Array indexes can be :

- 1) integer number where negative integers are counts from the end
- 2) ^ character which points to the first element
- 3) \$ character which points to the last element
- 4) next expression which can be evaluated to a 1), 2), 3)

It's possible to specify indexes range.  
Also it's possible to specify a multiple indexes/ranges in a single brackets pair.

Let's consider examples for the following next source code snippet

```

1 |
2 | fruits = ['Mango', 'Banana', 'Orange', 'Annona', 'Grape'];
3 |
4 | item = 3;
5 | item1 = -1;
6 | item2 = '$';
7 | text = 'hello';
8 |
9 | obj = {};
10 |

```

next expression	Explanation and result
<code>\${fruits[0]}</code> <code>\${fruits[^]}</code>	Resolves first array element The result is <code>'Mango'</code>
<code>\${fruits[\$]}</code>	Resolves last array element The result is <code>'Grape'</code>
<code>\${fruits[-1]}</code>	Resolves second array element from the end The result is <code>'Annona'</code>
<code>\${fruits[0..1]}</code> <code>\${fruits[^..1]}</code>	Resolves array elements range from 0 to 1 The result is <pre> 1   2   ["Mango", "Banana"] 3   </pre>
<code>\${fruits[^..2]}</code>	Resolves array elements range from first to third from the end The result is <pre> 1   2   ["Mango", "Banana", "Orange"] 3   </pre>
<code>\${fruits[1..-1]}</code>	Resolves array elements range from the second to second element from the end The result is <pre> 1   2   ["Banana", "Orange", "Annona"] 3   </pre>
<code>\${fruits[-2..\$]}</code>	Resolves array elements range from third from the end to the last element The result is <pre> 1   2   ["Orange", "Annona", "Grape"] 3   </pre>
<code>\${fruits[0..\$]}</code> <code>\${fruits[^..\$]}</code>	Resolves array elements range from the first to the last The result is <pre> 1   2   ["Mango", "Banana", "Orange", "Annona", "Grape"] 3   </pre>
	Resolves first, third and last array elements

<code>\${fruits[^, 2, \$]}</code>	<p>The result is</p> <pre>1   2   ["Mango", "Orange", "Grape"] 3  </pre>
<code>\${fruits[^, 1..2, \$]}</code>	<p>Resolves first array element, range from second to third and last element</p> <p>The result is</p> <pre>1   2   ["Mango", "Banana", "Orange", "Grape"] 3  </pre>
<code>\${fruits[ \${item} ]}</code>	<p>Resolves array element with index provided by <code>\${item}</code>.</p> <p>The result is</p> <p>'Annona'</p>
<code>\${fruits[ 0, \${item1}..\${item2} ]}</code>	<p>Resolves first array element and range provided by <code>\${item1}</code> and <code>\${index2}</code> indexes</p> <p>The result is</p> <pre>1   2   ["Mango", "Annona", "Grape"] 3  </pre>
<code>\${fruits[ \${text} ]}</code>	<p>Error message. Array index must be an integer or one of the following strings '^', '\$'</p>
<code>\${obj[3]}</code>	Accessing array elements action is ignored for objects and other non-array data types

### Substring [...]

ACTION\_ID is [ which ends with ]  
ACTION\_VALUE is located between [...] square brackets  
Applies for strings

All rules are same to array elements access from previous section.

Let's consider few examples for the following nextl source code snippet

```
1 |
2 | text = 'Hello, World !';
3 |
```

nextl expression	Explanation and result
<code>\${text[ 0 ]}</code> <code>\${text[ ^ ]}</code>	<p>Resolves first character</p> <p>The result is</p> <p>'H'</p>
<code>\${text[ 5, 13 ]}</code>	<p>Resolves character number 6 and 14 ( count starts from zero ). This action produces array of characters</p> <p>The result is</p> <pre>1   2   [",", " "] 3  </pre>
<code>\${text[ 5, 13 ]&amp;}</code>	<p>Same to a previous example but here we are joining all array element with empty string by using of &amp; action</p> <p>The result is</p> <p>'!'</p>
<code>\${text[ ^..4, 7..-2 ]}</code>	<p>Cuts the 'Hello' and 'World' words from the <u>text</u></p> <p>The result is</p> <pre>1   2   ["Hello", "World"] 3  </pre>
<code>\${text[ ^..4, 7..-2 ]&amp; }</code>	<p>Cuts the 'Hello' and 'World' words from the <u>text</u> and joins them with space</p> <p>The result is</p> <p>'Hello World'</p>

### Function call ()

ACTION\_ID is ( which ends with )  
ACTION\_VALUE is located between (...) parentheses  
Applies for functions

To perform additional data manipulations you can call a JavaScript functions directly from nextl expressions.  
For example if you need to perform array sort with special rules :

```
 ${arraySpecialSort( ARGUMENTS_LIST... )}
```

Where `arraySpecialSort()` is a JavaScript function.

Here `ARGUMENTS_LIST` can be only next expressions comma delimited as following ( spaces are ignored )

```
 ${arraySpecialSort( ${item1}, ${item2}, ... )}
```

To pass a constant value to the function use next expression with default value action :

```
 ${@hello}
 ${@79:num}
```

Function call with constant values as arguments :

```
 ${arraySpecialSort( ${@hello}, ${@79:num} )}
```

Function call examples

next expression	Explanation and result
<p>next source</p> <pre><code>1   2 - function arraySpecialSort(arr1, rules) { 3   // function stuff goes here... 4   return result; 5 } 6</code></pre> <p>next expression</p> <pre><code> \${arraySpecialSort( \${obj1~K}, \${x} )}</code></pre>	<p>In this example we are calling a <code>arraySpecialSort()</code> function and passing to a function two following arguments :</p> <pre><code> \${obj1~K}  \${x}</code></pre>
<pre><code> \${Math.round( \${value} )}</code></pre>	<p>Calling a standard <code>Math.round()</code> function and passing a <code> \${value}</code> argument</p>
<pre><code> \${Math.round( \${Math.PI} )}</code></pre>	<p>Calling a standard <code>Math.round()</code> function and passing a <code> \${Math.PI}</code> argument.</p> <p>The result is</p> <pre><code> 3</code></pre>
<pre><code> \${Math.round( \${@3\14:num} )}</code></pre>	<p>Calling a standard <code>Math.round()</code> function and passing a <code>3.14</code> constant value</p> <p>Let's take a closer look to a <code> \${@3\14:num}</code> expression. In the <code> \${@3\14:num}</code> expression we must escape a dot not to be treated as object property resolution action. <code>:num</code> casts a '3.14' string value to numeric</p> <p>The result is</p> <pre><code> 3</code></pre>

`next.nextlize()` global function gives you ability to use a next API from inside your custom JavaScript function.

Function definition :

```
 next.nextlize(nextExpression, args)
```

`nextExpression` can be a string, array or object which are contain internal next expression. `nextlize()` function will expand those internal expressions

`args` is optional object to override data elements in next source. See more about external arguments [here](#)

Example :

```
1 |
2 - function callNextAPI( arg1, arg2 ) {
3   // function stuff...
4   var result = next.nextlize( "${obj1~V}", { ENV: 'dev' } );
5   return result;
6 }
7
```

## System and user functions

Functions declared under `next.system.functions` and `next.user.functions` are global and accessible directly in next expressions without prefix.

next provides set of useful functions under `next.system.functions` object.

Do not override that object. Declare your custom functions under the `next.user.functions` to extend your code.

For example :

```
1 |
2 - next.user.functions.increase = function (num) {
3   return num++;
4 };
5
```

You can call a `increase()` function in two ways :

```
1) ${increase( ${item} )}
2) ${next.user.functions.increase( ${item} )}
```

List of system functions

```

replaceAll(entity, searchItem, replaceItem)
  replaces all searchItem elements in array or all searchItem characters in string with replaceItem

not(param)
  inverts boolean

makeObj(key, value)
  makes new JavaScript object. If key is not provided the object will be empty

isContains(entity, item)
  if entity array contains item or string entity contains item, returns true, otherwise false

isEquals(entity1, entity2)

isBool(item)

isStr(item)

isNum(item)

isNull(item)

isUndefined(item)

isPrimitive(item)

isArray(item)

isObject(item)

ifContains(entity, item, thenIf, elseIf)
  if entity array contains item or string entity contains item, returns thenIf, otherwise returns elseIf

ifEquals(entity1, entity2, thenIf, elseIf)

ifBool(item, thenIf, elseIf)

ifStr(item, thenIf, elseIf)

ifNum(item, thenIf, elseIf)

ifNull(item, thenIf, elseIf)

ifUndefined(item, thenIf, elseIf)

ifPrimitive(item, thenIf, elseIf)

ifArray(item, thenIf, elseIf)

ifObject(item, thenIf, elseIf)

```

### Pushing value to function parameters stack |

ACTION\_ID is |  
ACTION\_VALUE - doesn't have a value

Each next expression has a special data stack. This data stack can be used when you call a function in next expression. In this case all values from that data stack are passed to function arguments ( stack arguments are passed prior to arguments described in function call in next expression ).

You can push values to the stack multiple times.  
After each push current chain value is reseted ( i.e. became undefined value ).  
Stack lives within next expression. After expression calculation stack is deleted.

Literally stack allows you to pass a value calculated by actions in next expression to the function for further calculations

Examples :

next expression	Explanation and result
<code>`\${obj} isObject()`</code>	1) Resolves <u>obj</u> object 2) Pushes it to the stack. This action resets current value in actions chain to <u>undefined</u> 3) Resolves a <u>isObject</u> function. It is a system function therefore it's available globally 4) Calls a <u>isObject()</u> function. This function gets a <u>obj</u> as argument because it was pushed to the stack  Expression in this example is same to the following expression <code>`\${isObject( \${obj} )}`</code>
<code>`\${item} isPrimitive() not()`</code>	Resolves <u>item</u> , pushes its value to the stack and then calls a <u>isPrimitive()</u> function. Function evaluation result is also pushed to the stack and then <u>not()</u> function inverts the result
<code>`\${item1} item2 ifEquals( \${a}, \${b} )`</code>	1) Resolves <u>item1</u> and pushes it to stack. 2) Resolves <u>item2</u> and pushes it to stack. 3) Calls a <u>ifEquals()</u> function.  The <u>ifEquals()</u> function accepts 4 arguments. First two arguments are taken from the stack and the followed arguments are taken from explicit function parameters as <u>`\${a}`</u> and <u>`\${b}`</u> . If <u>item1</u> and <u>item2</u> equals the result will be <u>`\${a}`</u> , otherwise <u>`\${b}`</u>
